1989–1991, Postdoctoral Associate, JISAO, University of Washington.

Abstract

One of the most enduring features of Earth's atmosphere is the jet stream, whose variability visibly affects daily weather and climate. The jet stream also acts as a conduit of large-scale eddies and waves that transport momentum (and through thermal wind balance, heat) and connect different parts of the atmosphere dynamically. In this talk, I will describe recent advances in understanding large meandering of the jet stream from synoptic, sub- seasonal to seasonal timescales. I will cover theoretical foundations as well as application of theory to reanalysis data, using atmospheric blocking and stratospheric sudden warming as examples.
